Using a Fermi-liquid approach, we provide a comprehensive treatment of the current and current noise through a quantum dot whose low-energy behavior corresponds to an SU(N) Kondo model, focusing on the case \(N=4\) relevant to carbon nanotube dots. We show that for general \(N\), one needs to consider the effects of higher-order Fermi-liquid corrections even to describe low-voltage current and noise. We also show that the noise exhibits complex behavior due to the interplay between coherent shot noise, and noise arising from interaction-induced scattering events. We also treat various imperfections relevant to experiments, such as the effects of asymmetric dot-lead couplings.

I. INTRODUCTION

The Kondo effect has long served as a paradigm in the field of strongly correlated electron physics. It is perhaps the simplest example of a system where many-body interactions can give rise to highly nontrivial behavior: its essence involves nothing more than a localized magnetic impurity which is exchange coupled to conduction electrons in a metal. Despite having been studied for over 40 years, interest in Kondo physics shows no sign of abating. A large part of this continued interest has been fueled by recent advances allowing the controllable realization of unusual Kondo effects in nanostructures. These include multichannel Kondo effects,1 where there are many conserved flavors of conduction electrons: such systems can give rise to non-Fermi-liquid physics and have recently been realized using semiconductor quantum dots.2 Another class of exotic Kondo effects are so-called SU\((N)\) Kondo effects, where \(N>2\). Such systems involve only a single channel of conduction electrons but the effective spin of the impurity and conduction electrons is greater than 1/2. While such systems are still described at low energies by a Fermi-liquid fixed point, the properties of this Fermi liquid are modified in several interesting ways compared to the spin-1/2 case.3 The case \(N=4\) has received particular attention due to its realizability in double4–6 and triple quantum dots7 as well as carbon nanotube quantum dots8–12.

Research on Kondo physics has also been spurred by the possibility of studying experimentally its behavior when driven out of equilibrium, where nonequilibrium is either achieved by the application of a drain-source voltage across a quantum dot13,14 or by externally radiating a quantum dot.15 The nonequilibrium induced by a voltage has been the subject of a number of recent theoretical works.16–22

In this paper, we will focus on a topic which combines two of the above avenues of Kondo research: we will study nonequilibrium charge transport through a voltage-biased quantum dot exhibiting an SU\((N)\) Kondo effect, focusing on the low-temperature regime where the physics is described by an effective Fermi-liquid theory. We present calculations for both the nonlinear conductance as well as for the current noise. As has been stressed in a number of recent papers,23–25 the fluctuations of current through a Kondo quantum dot are extremely sensitive to the two-particle interactions associated with the underlying Fermi-liquid theory. This was first discussed in the case of the standard SU(2) Kondo effect by Sela et al.,23 and was even measured for this system in a recent experiment by Zarchin et al.26 As discussed in Refs.24 and 25, the situation becomes even more interesting for \(N>2\), as now one must deal with the interplay between coherent partition noise (due to the zero-energy transmission coefficient through the dot not being one) and the interaction-induced scattering events. Of particular interest is the case \(N=4\), which can be realized in carbon nanotube quantum dots. Very recently, current noise in such a system has been measured experimentally by Delattre et al.,27 though not in the low-temperature Fermi-liquid regime we describe here.

The results presented here both clarify and extend those presented in Refs.24 and 25 as well as provide details underlying the calculational approach. Particular attention is given to the role of higher-order Fermi-liquid corrections, something that was not correctly treated in previous works (see erratum, Ref. 28). We show clearly how in the \(N=4\) case, such corrections lead to an effective shift of the Kondo resonance with applied bias voltage. As a result, the nonlinear conductance does not increase with voltage, as would be expected from a simple picture of the Kondo resonance as a resonant level sitting above the Fermi energy. These Fermi-liquid energy shifts are absent in the usual \(N=2\) Kondo effect. We also describe the experimentally relevant case where there is an asymmetry in the coupling between the quantum dot and the source and drain electrodes. Such an asymmetry has not been investigated thoroughly in previous works.

The remainder of this paper is structured as follows. In Sec. II, we outline the basic description of our model and the Fermi-liquid approach. Secs. III and IV are devoted to providing a detailed discussion of our results for both the con-
ductance and the shot noise as well as details on their derivation. In Sec. V, we summarize our main results for the conductance and shot noise of a SU(N) Kondo quantum dot, and conclude.

II. MODEL DESCRIPTION

A. Kondo Hamiltonian

We give here a compact synopsis of the quantum-dot model we study and how it gives rise to Kondo physics. The dot connected to the leads is described by the following Anderson Hamiltonian\textsuperscript{29}

\[
H = H_D + H_L + H_T
\]

\[
= \epsilon_D \sum_{\sigma} n_{\sigma} + U \sum_{\sigma \neq \sigma'} n_{\sigma} n_{\sigma'} + \sum_{k, \sigma} \epsilon_k (c_{k, \sigma}^\dagger c_{k, \sigma} + c_{k, \sigma}^\dagger c_{k, \sigma}) + \sum_{k, \sigma} (t_{L,R} c_{k, \sigma}^\dagger d_{\sigma} + H.c.)
\]

\[
(c_{L,R,\sigma}) \text{ is the annihilation operator for an electron of spin } \sigma \text{ on the dot. The lead electrons transform under the fundamental representation of SU}(N)\text{ and SU}(N) \text{ while the transition energy is quenched to an integer value and does not fluctuate. For this energy, the charge degree of freedom on the dot is described by the Kondo Hamiltonian (3) in terms of current, Affleck}^{34} \text{ has shown by completing the square that the impurity spin can be absorbed by lead electrons. The resulting (conformal field) theory is that of free fermions and it is believed to be the strong-coupling fixed point that dominates at low energy is a Fermi-liquid one.}

B. Fermi-liquid theory

We now discuss in detail the Fermi-liquid theory for the Kondo effect, first introduced by Nozières.\textsuperscript{36} It describes the low-energy regime—the vicinity of the strong-coupling fixed point and allows one to make quantitative predictions even in an out-of-equilibrium situation. In Ref. 3, the Fermi-liquid theory of Nozières has been extended with the introduction of the next-to-leading-order corrections to the strong-coupling fixed point. These corrections are necessary in the SU(N) case for observables like the current and the noise since their energy (\(k_{BG}, eV\)) or dependence (\(\mu G\)B) is mostly quadratic.

The Kondo many-body singlet (also called the “Kondo cloud”) having been formed, we wish to describe how lead electrons scatter off it. At low energies, two channels open:
an elastic and an inelastic one. Both take place at the dot position $x=0$. Elastic scattering is described by an energy-dependent phase shift. At the Fermi level $e_F$, it is equal to $\delta_0$, see Eq. (5). We expand the phase shift around the Fermi energy
\[ \delta_{el}(\varepsilon) = \delta_0 + \frac{\alpha_1}{T_K} \varepsilon + \frac{\alpha_2}{T_K^2} \varepsilon^2, \] (6)
where the energy $\varepsilon$ is measured from $e_F$. $\alpha_1$ and $\alpha_2$ are dimensionless coefficients of order one.

It is instructive to think of the elastic scattering off the Kondo singlet in terms of an effective noninteracting resonant-level model (RLM), where this effective resonance represents the many-body Kondo resonance. This is the picture of the Kondo effect provided by slave-boson mean-field theory$^{33}$ and is an exact description of the SU($N$) Kondo effect in the large $N$ limit.$^{36}$ Note that for finite $N$, one must also deal with two-particle scattering off the singlet, something that will never be captured by the RLM; we thus only use it to obtain insight into the elastic-scattering properties. In the RLM picture, the first two terms in the phase shift in Eq. (6) are attributed to a Lorentzian scattering resonance centered at $e_K=T_K \cot \delta_0$ with a width $\propto T_K$.\textsuperscript{25} In the SU(4) case, one thus finds that the Kondo resonance is centered at a distance $e_K=T_K$ above the Fermi energy, giving a heuristic explanation for the fact that the low-energy transmission coefficient through the dot is only $T=1/2$. The fact that the Kondo resonance sits above the Fermi energy is indeed seen in exact NRG calculations of the impurity spectral density.$^{8,10}$

The low-energy expansion of the RLM phase shift $\delta(\varepsilon)$ = $\arctan(\frac{T_K}{\varepsilon-e})$ also gives the form Eq. (6) with $\alpha_2/\alpha_1^2 = \cot \delta_0$. Note that there is no apriori reason that this relation must hold for the expansion of the true phase shift, as the correspondence to a noninteracting resonant level is not exact. Despite this caveat, one finds that the prediction from the RLM picture is quite good even at a quantitative level. The RLM result is indeed the elastic phase shift in Eq. (6).\textsuperscript{21} This point will be expanded on in Sec. III when we discuss the calculation of the current.

We turn now to inelastic effects, which arise from quasiparticle interactions in the Fermi-liquid theory. These interactions can be written in a Hamiltonian form$^3$
\[ H_{\text{int}} = \frac{\phi_1}{\pi \nu^2 T_K} \sum_{\sigma<\sigma'} \langle b_{\sigma \delta}^\dagger b_{\sigma' \delta}^\dagger b_{\sigma' \delta} b_{\sigma \delta} \rangle, \] (9)
where $\cdot \cdot$ denotes normal ordering and $\nu=1/(\hbar v_F)$ is the density of state for one-dimensional fermions moving along one direction. To summarize, the Fermi-liquid theory is generated by the Hamiltonian $H=H_0+H_{\text{int}}$, given by Eqs. (8) and (9), with the elastic phase shift Eq. (6). In fact, Eqs. (6) and (9) correspond to a systematic expansion of the energy,$^3$\textsuperscript{36} compatible with the SU($N$) symmetry and the Pauli principle. It includes all first and second-order terms in the low-energy coupling strength $\propto 1/T_K$.

The great advantage of the Fermi-liquid approach is that it can also be applied to nonequilibrium situations. Note that the Fermi level $e_F$ appears twice in the above equations: it defines the reference for energies in the elastic phase shift Eq. (6) and also for the normal ordering in Eq. (9). When the system is put out of equilibrium, for instance when each lead has its own Fermi level, $e_F$ loses its meaning as a Fermi level and becomes merely an absolute energy reference. This can be used to relate$^3$ the coefficients $(\alpha_1, \alpha_2, \phi_1, \phi_2, \chi_2)$ as we shall show below.

### C. Kondo floating and perturbation theory
To make progress in calculating physical observables at low energies, we will treat the interacting part $H_{\text{int}}$ [cf. Eq. (9)] of the Fermi-liquid Hamiltonian perturbatively. Among the various diagrams built from Eq. (9), it is convenient to separate the trivial Hartree contributions to the electron self-energy from the more complicated diagrams. The former are obtained by keeping an incoming and an outgoing line and by closing all other external lines to form loops as shown Fig. 1. The resulting diagrams are then in correspondence with the diagrams describing scattering by a local potential. Therefore they can be included in the elastic phase shift
The structure of this resonance is therefore changing with the Fermi-liquid corrections. However, for transport quantities in the general SU(2) case also used this idea but restricted attention to an initial state with no quasiparticles. Equations (11b) follow when we apply the same reasoning to an initial state having some finite number of quasiparticles. Note that for SU(2), or a half-filled dot \((n=N/2)\), \(\alpha_2=0\) from Eq. (7) so that \(\phi_2=0\) and \(\chi_2=0\). The next-to-leading-order corrections all vanish in agreement with previous works on the ordinary SU(2) case.

It is worth mentioning that the second generation of Fermi-liquid terms \((\alpha_2, \phi_2, \chi_2)\) can also be derived in the framework of conformal field theory. In Ref. 3, a single cubic Casimir operator is given, which reproduces the three terms corresponding to the coefficients \(\alpha_2\), \(\phi_2\), and \(\chi_2\). The identities (11b) are then automatically satisfied.

The floating of the Kondo resonance (and resulting conditions) also has an important consequence for calculations of observables in the presence of a voltage: the results will not depend on where one decided to place the dot Fermi energy \(e_F\) within the energy window defined by the chemical potentials of the leads. On a technical level, this is because, by virtue of Eqs. (11), any shift \(\delta e_F\) of the dot Fermi energy will be completely compensated by a corresponding shift in the Hartree contributions arising from the quasiparticle interactions. This invariance is explained in detail in Fig. 2. Note also that this invariance has physical consequences as well: it implies, for example, that the current is not affected by the capacitive coupling to the leads (in the Kondo limit).

Given the above invariance, it is convenient for calculations to choose the Fermi level such that

\[
\delta n_{0,\sigma} = \int d\epsilon \delta n_{\gamma}(\epsilon) = 0
\]

so that any closed fermionic loop built from an energy-independent vertex vanishes. For this choice of position, \(\delta n_{0,\sigma}\) vanishes which greatly simplifies the phase shift expression (10). Moreover, the \(\chi_2\) vertex in Eq. (9) does not contribute to the current and the noise when the perturbative calculation is stopped at second order. The reason for that is that the \(\chi_2\) vertex is already second order and can only appear once. Its six legs are connected to at most two current vertices so that at least two of these legs must connect to form a closed loop implying a vanishing contribution. In contrast to these simplifications, \(\delta E_{1,\gamma}\) in Eq. (10) remains generally different from zero due to the energy dependence of the \(\phi_2\) vertex in Eq. (9).

On may wonder whether the physical argument of the

\[
\alpha_1 = (N-1)\phi_1, \quad (11a)
\]

\[
\alpha_2 = \frac{N-1}{4} \phi_2, \quad \phi_2 = (N-2)\chi_2, \quad (11b)
\]
floating of the Kondo resonance, as presented in Ref. 3 and repeated in this paper, is sufficient to extend the results of this paper to higher orders Fermi-liquid corrections. Applying the floating argument to the next (third) order, one obtains an incomplete set of relations between the coefficients such that some of them remain undetermined. In the language of conformal field theory, it means that more than one operator is involved at each (higher) order. How to relate the coefficients of those operators is a rather difficult problem. In the SU(2) case, a solution was given by Lesage and Saleru.44

We finally turn to the discussion of the Fermi-liquid-model renormalization. Treated naively, the model leads to divergences in physical quantities. It is regularized31 by introducing an energy cutoff D (different from the original band width of the model) larger than typical energies of the problem but smaller than TF. Energies in Eq. (8) are therefore restricted to the window [−D,D]. The dependence of observables in D is then removed by adding counterterms in the Hamiltonian. It is strictly equivalent to the introduction of cutoff D dependence in the coupling constants (α, φ, etc.). The corresponding counterterms are discussed in Appendix A.

III. CURRENT CALCULATION

We now outline the calculation of the current using the Fermi-liquid theory described in previous sections. Again, the complete Hamiltonian is $H=H_0+H_{\text{int}}$ [cf. Eqs. (8) and (9)], corresponding, respectively, to elastic and inelastic scattering; the approach will be to treat $H_{\text{int}}$ as a perturbation. Slightly abusing terminology, we will include all Hartree contributions arising in perturbation theory in the free Hamiltonian $H_0$. $H_0$ will thus correspond to the elastic phase shift given in Eq. (10). Contributions to the current which only involve $H_0$ (thus defined) will be referred to as the “elastic current.” $H_{\text{int}}$ is then added perturbatively, without Hartree diagrams, in order to compute the corrections due to inelastic scattering.

A. Current operator

The current operator at $x$ is generally given by

$$\hat{J}(x) = \frac{e\hbar}{2mi} \sum_\sigma \left[ \partial_t \psi_\sigma(x) \bar{\psi}_\sigma(x) - \bar{\partial}_t \psi_\sigma^\dagger(x) \psi_\sigma(x) \right],$$

where $m$ is the electron mass. Various expressions can be obtained for the current depending on which basis it is expanded. It is convenient44 in our case to choose the basis of scattering states that includes completely elastic (and Hartree terms) scattering, i.e., the phase shift Eq. (10) and that correspond to eigenstates of the single-particle scattering matrix. Such states will have waves incident from both the left and right leads. This is in contrast to another standard choice,25 which is to use scattering states which either have an incident wave from the left lead, or from the right. We refer to such states as the “left/right” states.

We first discuss our scattering states in first quantization. Eigenfunctions corresponding to the $a_{\kappa\sigma}$ variables do not see the dot or the Kondo effect. Using Eq. (2), they read

$$\psi_{\kappa\sigma}(x) = \begin{cases} \sin \theta(e^{i(\beta_{\kappa\sigma}^L)x} - e^{-i(\beta_{\kappa\sigma}^L)x}) & x < 0 \\ \cos \theta(e^{i(\beta_{\kappa\sigma}^L)x} - e^{-i(\beta_{\kappa\sigma}^L)x}) & x > 0, \end{cases}$$

where $\theta = \pi/4$ measures the asymmetry of the coupling to the leads, see Eq. (2), and the eigenenergies $\hbar\nu_{\kappa\sigma}k$ are measured from the Fermi level $e_F$. The situation is more complicated for the $b_{\kappa\sigma}$ variables. The associated eigenfunctions at small $x$, close to the dot, depend on the complex ground-state wave function of the Kondo problem. They are not known and in fact it cannot even be reduced to a one-particle problem. However, we can write the eigenfunctions far from the dot

$$\psi_{b\kappa\sigma}(x) = \begin{cases} \cos \theta(e^{i(\beta_{\kappa\sigma}^R)x} - S S_e^{-i(\beta_{\kappa\sigma}^R)x}) & x < 0 \\ \sin \theta(e^{i(\beta_{\kappa\sigma}^R)x} - S S_e^{-i(\beta_{\kappa\sigma}^R)x}) & x > 0, \end{cases}$$

where the $S$ matrix is related to the phase shift Eq. (10), $S_e = e^{\text{i}S(\alpha_0)}$ at eigenenergy $e_0 = \hbar\nu_{\kappa\sigma}k$. The eigenstates Eqs. (14) and (15) have the same energy. They can be combined to give the left and right scattering states with the energy-dependent transmission $T(e) = \text{sin}^2(2\text{sin}^{-1}[\mathcal{S}(e)])$. In the SU(2) case (or generally particle-hole symmetric case), $\alpha_0 = \pi/2$ and the system is closed to unitarity for symmetric leads coupling.

We come back to second quantization and project the electron operator $\psi_{\kappa\sigma}(x)$ over the eigenstates Eqs. (14) and (15). Conservation of the current implies that $\hat{J}(x)$ does not depend on $x$. We choose an arbitrary $x<0$ far from the dot,
\[^{\hat{I}_{\text{L}}, \text{the current at } x \text{ and } \hat{I}_{\text{R}} \text{ at } -x. \text{ If } \hat{I} \text{ denotes the conserved current, } \hat{I} = \hat{I}_{\text{L}} = \hat{I}_{\text{R}}. \text{ The combination } \sin^2 \theta \hat{I}_{\text{L}} + \cos^2 \theta \hat{I}_{\text{R}} \text{ leads to the compact expression}
\]
\[\hat{I} = \frac{e}{2vh} \sum \{ \sin 2\theta (a_{\sigma}^\dagger(x)b_{\sigma}(x) - a_{\sigma}^\dagger(-x)b_{\sigma}(-x)) + \text{H.c.} \}
\]
\[+ 2 \cos 2\theta (a_{\sigma}^\dagger(x)a_{\sigma}(x) - a_{\sigma}^\dagger(-x)a_{\sigma}(-x)) \] (16)
\[\text{with } b_{\sigma}(x) = \sum \alpha_\lambda c_{\lambda \sigma} e^{i k x} \text{ and } S b_{\sigma}(x) = \sum \alpha_\lambda S \alpha_\lambda e^{i k x}. \text{ Physically, operators taken at } x(\pm x) \text{ correspond to incoming (outgoing) states.}\]
\[\text{The second line in Eq. (16) turns out not to contribute to the mean current, the noise or any moment of the current.}
\]
\[\text{Before proceeding with the calculation, it is worth noting that in the SU(2) case, the proximity to the unitary situation allows a simpler treatment.}\]
\[\text{The current is written } \hat{I} = I_u - \hat{I}_{\text{RS}} \text{ with } I_u = \frac{e^2}{2C} V. \text{ All quantum or thermal fluctuations are included in the backscattering current } \hat{I}_{\text{RS}} \text{ which can be written in terms of } \alpha_\lambda \text{ and } b_{\lambda \sigma} \text{ operators.} \]
\[\text{However, the range of application of this approach is restricted to the SU(2) case with a completely symmetric leads coupling. In any other situations neglecting fluctuations in } I_u \text{ is incorrect and Eq. (16) becomes necessary.}
\]
\[\text{B. Elastic contribution to the current}
\]
\[\text{We are now in a position to compute the mean value of the current in an out-of-equilibrium situation. A de bias is applied between the two electrodes imposing } \mu_L - \mu_R = eV. \text{ Left and right scattering states, corresponding to } c_{L,\lambda \sigma} \text{ and } c_{R,\lambda \sigma} \text{ operators, are in thermal equilibrium with chemical potentials } \mu_L \text{ and } \mu_R. \text{ Hence, using Eq. (2), we obtain the populations}
\]
\[\langle b_{\lambda \sigma}^\dagger b_{\lambda \sigma} \rangle = \delta_{L,\lambda} \left[ \cos^2 \theta \sigma f_{\lambda}(\epsilon_k) + \sin^2 \theta \sigma f_{R}(\epsilon_k) \right], \] (17a)
\[\langle a_{\lambda \sigma}^\dagger a_{\lambda \sigma} \rangle = \delta_{L,\lambda} \left[ \sin^2 \theta \sigma f_{L}(\epsilon_k) + \cos^2 \theta \sigma f_{R}(\epsilon_k) \right], \] (17b)
\[\langle a_{\lambda \sigma}^\dagger b_{\lambda \sigma} \rangle = \langle b_{\lambda \sigma}^\dagger a_{\lambda \sigma} \rangle = \delta_{L,\lambda} \sin 2\theta \frac{1}{2} \left[ f_{L}(\epsilon_k) - f_{R}(\epsilon_k) \right], \] (17c)
\[f_{L,R}(\epsilon) = f(\epsilon - \mu_{L,R}) \] (17d)
\[\text{for all spins } \sigma. \text{ Equation (12), that implies a vanishing Hartree diagram, is satisfied with } \mu_L = \cos^2 \theta \epsilon \text{ and } \mu_R = \cos^2 \theta \epsilon \text{.} \]
\[\text{The average current is obtained from Eq. (16) and reproduces the Landau-Büttiker formula}\]
\[I_{\text{el}} = \frac{Ne}{h} \int_{\epsilon_{\text{min}}}^{\epsilon_{\text{max}}} d\epsilon T(\epsilon) \left[ f_{L}(\epsilon) - f_{R}(\epsilon) \right] \] (18)
\[\text{with the transmission}
\]
\[T(\epsilon) = \sin^2 2\theta \sin^2 \theta \delta(\epsilon) \] (19)
\[\text{and the phase shift}
\]
\[\delta(\epsilon) = \delta_0 + \frac{\alpha_1}{T_K} \sin^2 \theta \frac{(\pi T)^2}{3} \left[ \sin^2 \theta \frac{(eV)^2}{4} \right], \] (20)
\[\text{where we have used the identity (11b), } \alpha_2 = (N-1)\phi_0/4. \text{ Here, the phase shift } \delta(\epsilon) \text{ has an extra } (V,T) \text{ dependence due to mean-field (Hartree) interaction contributions [cf. Eq. (10)]. Within the heuristic resonant-level picture, we can interpret this as the voltage inducing a quasiparticle population, whose interactions in turn yield a mean-field upward energy shift of the Kondo resonance. Note that the relevant interactions here are not the leading-order Fermi-liquid interactions described by } \phi_1 \text{ but rather the next-leading-order interaction described by } \phi_2.
\]
\[\text{At zero temperature, the current can be expanded to second order in } eV/T_K. \text{ The asymmetry and the zero-energy transmission are characterized by}
\]
\[C = \cos 2\theta, \quad T_0 = \sin^2 \theta \delta_0 \] (21)
\[\text{with } C = 0 \text{ in the symmetric case. The current takes the form}
\]
\[\frac{I_{\text{el}}}{(1 - C^2)N e^2 V h} = T_0 - C \sin 2\delta_0 \frac{eV}{2T_K} \left[ \frac{eV}{T_K} \right]^2 \times \left[ \cos 2\delta_0 (1 + 3C^2) \frac{\alpha_1}{12} \right. - \left. \sin 2\delta_0 (1 - 3C^2) \frac{\alpha_2}{6} \right]. \] (22)
\[\text{C. Inelastic contribution to the current}
\]
\[\text{The Keldysh framework is well suited to estimate interaction corrections Eq. (9) to the current. The mean current takes the form}
\]
\[I = \left\langle T \hat{J}(t)e^{-i\hat{H}_t}\hat{d}^\dagger(t')H_{\text{int}}(t') \right\rangle, \] (23)
\[\text{where the Keldysh contour } C \text{ runs along the forward time direction on the branch } \eta = + \text{ followed by a backward evolution on the branch } \eta = -. T_t \text{ is the corresponding time-ordering operator. Time evolution of } \hat{J}(t) \text{ and } H_{\text{int}}(t) \text{ is in the interaction representation with the unperturbed Hamiltonian } H_0. \]
\[\text{Mean values } \langle ... \rangle \text{ are also taken with respect to } H_0 \text{ Eq. (8) with bias voltage, see Eqs. (17). Note that the time } t \text{ in Eq. (23) is arbitrary for our steady-state situation. Finally, in order to maintain the original order of operators in } \hat{J}(t), \text{ we take left (creation) operators on the } \eta = - \text{ branch and right (annihilation) one on the } \eta = + \text{ branch.}
\]
\[\text{A perturbative study of Eq. (23) is possible by expansion in } H_{\text{int}} \text{ and use of Wick's theorem. This leads to useful diagrammatics where one should keep track of the Keldysh branch index. The lowest order recovers the results of Sec. III B describing elastic scattering. The next first order gives only Hartree terms already included in Eq. (22). } H_{\text{int}} \text{ gives rise in general to three vertices with coefficients } \phi_1, \phi_2, \text{ and } \chi_2 \text{ where the last two are already second order in } 1/T_K. \text{ Thus it is consistent to keep only } \phi_1 \text{ in the second-order expansion in } H_{\text{int}}. \text{ A typical Green's function is defined by } \Phi_{\eta} = H_{\text{int}} \phi_1 \text{ and } \chi_2.
\]
The second-order correction from Eq. \( H_{20849} \) to the current from Hamiltonian \( H_{20849} \) is given by Eq. \( (21) \) and \( J_{\pm} \) is \( \frac{1}{4} \) \( C \) for \( t \neq 0 \)

\[
\sum_{\eta_1,\eta_2} \left[ G_{bb}(k,\varepsilon) + G_{bb}(k,\varepsilon) \right] \delta(\varepsilon - \varepsilon_k)
\]

Similarly, for \( t \neq 0 \)

\[
\sum_{\eta_1,\eta_2} \left[ G_{bb}(k,\varepsilon) + G_{bb}(k,\varepsilon) \right] \delta(\varepsilon - \varepsilon_k)
\]

The causality identity, for \( t \neq 0 \)

\[
\Sigma^{+}(t) + \Sigma^{-}(t) = \Sigma^{+}(t) + \Sigma^{-}(t)
\]

is derived by writing the explicit time dependence in Eq. \( (25) \). It leads to various calculations, in particular, for terms where the lines external to the self-energy Eq. \( (25) \) bear no \( \eta_{1/2} \) dependence. The lines that join the current vertex to the self-energy in Fig. 3 travels from \( x \) (or \( -x \)) to \( 0 \) (the dot) and the opposite. Thus, using the Green’s function \( (24a) \) in real space (with \( \alpha = \pm 1 \))

\[
G_{bb}(k,\varepsilon) = i\pi\theta(\varepsilon - \varepsilon_k) F(\varepsilon) + \eta_1 \frac{\alpha = 1}{\eta_2 \alpha = -1} \xi(\varepsilon)
\]

and the identity \( (26) \), one shows that the terms with operators taken at \( x \) in Eq. \( (16) \) give a vanishing contribution to the current. This is merely a consequence of causality: interaction, which takes place at \( x = 0 \), can only affect outgoing current and not the incoming part. We are left with the current correction

\[
\frac{\partial I_{\text{int}}}{\partial N} = \frac{N(N-1)e}{2\pi} \sin 2\phi \left( \frac{\phi_1}{\pi \nu T_K} \right)^2 \sum_{\eta_1,\eta_2} \eta_1 \eta_2 \times \int \frac{d\varepsilon}{2\pi} [\mathcal{S}G_{bb}^\eta_1(\varepsilon)] \mathcal{S}G_{bb}^\eta_2(\varepsilon) + \text{c.c.}.
\]

(28)

The summation over \( \eta_1 \) and \( \eta_2 \) gives two terms: (i) one includes the combination \( \Sigma^{+} - \Sigma^{-} \). It gives a contribution proportional to \( D \) exactly cancelled by a counterterm. Details are given in Appendix A. (ii) The second term involves the combination \( \Sigma^{+} + \Sigma^{-} \) and remains finite in the limit \( D \to +\infty \). It reads

\[
\frac{\partial I_{\text{int}}}{\partial N} = \frac{N(N-1)(1-C^2)e}{2\pi} \sin 2\phi \left( \frac{\phi_1}{\pi \nu T_K} \right)^2 \times (S + S^*) \int \frac{d\varepsilon}{2\pi} [\mathcal{S}G_{bb}^{\eta_1}(\varepsilon)] \mathcal{S}G_{bb}^{\eta_2}(\varepsilon) + \text{c.c.}
\]

(29)

with \( C \) given by Eq. \( (21) \) and \( J_{\pm} \) is \( \frac{1}{4} \) \( C \) for \( t \neq 0 \). We proceed further and restrict ourselves to the zero-temperature case. The left and right Fermi-step functions are introduced by going to frequency space for Eq. \( (25) \) and then by using Eqs. \( (24a) \) and \( (17) \). The result involves a sum of terms with products of \( \cos^2 \theta \) and \( \sin^2 \theta \). Two distinct integrals

\[
J_1 = \int_{\mu_L} \int_{\mu_R} d\varepsilon' \int_{\mu_L} \int_{\mu_R} d\varepsilon'' f_1(\varepsilon + \varepsilon' - \varepsilon'')
\]

(30a)

\[
J_2 = \int_{\mu_L} \int_{\mu_R} d\varepsilon' \int_{\mu_L} \int_{\mu_R} d\varepsilon'' f_1(\varepsilon + \varepsilon' - \varepsilon'')
\]

(30b)

corresponding, respectively, to one- and two-particles transfer, appear with the following combination:

\[
\cos^2 \theta \sin^2 \theta J_2 - 2J_1 + J_1 = \frac{J_2(1-C^2) + 2J_1(1+C^2)}{4}
\]

(31)

With \( J_1 = (eV)^3/6 \) and \( J_2 = 4(eV)^3/3 \), we obtain the current correction

\[
\frac{\partial I_{\text{int}}}{\partial N} = \cos 2\delta(\varepsilon) \left( \frac{\phi_1}{T_K} \right)^2 \left( \frac{5}{12} \frac{C^2}{4} \right)
\]

(32)

This result can be given a quite simple physical interpretation along the line of Ref. 23. The \( \phi_1 \) term in the interaction part of the Hamiltonian \( (9) \) can be decomposed on the left/right operators basis using Eq. (2). It then describes processes where 0, 1, or 2 electrons are transferred from one scattering state to the other. Using Fermi’s golden rule and \( \cos \theta \sin^2 \theta + \cos^2 \theta \sin^6 \theta = (1-C^2)/8 \), the total rate of one-electron transfer is evaluated to be \( 2\Gamma_1(1-C^2) \) where

\[
\Gamma_1(1-C^2)
\]
\[ \Gamma_1 = N(N-1) \frac{e^2 \phi^2}{h} \frac{e^2 V}{24} \left( \frac{e^2 V}{2} \right)^2. \]  

(33)

From \( \cos^4 \theta \sin^4 \theta \approx (1-C^2)^2/16 \), the total rate for two-electron transfer is \( \Gamma_2(1-C^2)^2/2 \) where \( \Gamma_2 = \Delta^2 \Gamma_1 \). For one- and two-electron transfers, \( e \cos \theta \delta_0 \) and \( 2e \cos \delta_0 \) are interpreted as the corresponding charge transferred between leads.\(^{25} \) Writing the current correction as

\[ \delta I_{\text{int}} = (e \cos \theta \delta_0) 2\Gamma_1(1-C^2) + (2e \cos \delta_0) \Gamma_2 \frac{1}{2} (1-C^2)^2, \]

we recover Eq. (32).

### D. Current for SU(2) and SU(4)

The results of Secs. III B and III C can be extended to finite temperature as explained in Appendix B. We detail results for the total current \( I = I_{\text{el}} + \delta I_{\text{int}} \) in the \((N=2, m=1)\) case, and \((N=4, m=1, 2)\) cases. For SU(2), a single electron is trapped on the dot, \( \alpha_1 = \phi_1 \) and \( \alpha_2 = 0 \). The current takes the form

\[ I = I_m \left( 1 - \left( \frac{\alpha_1}{T_K} \right)^2 \left( \frac{e^2 V}{2} + \pi T \right)^2 \right), \]

\[ (34) \]

where \( I_m = (2e^2V/h)(1-C^2) \). In the particle-hole SU(4) symmetric case with two electrons, \( \alpha_1 = 3\phi_1 \) and \( \alpha_2 = 0 \). The current reads

\[ I = I_m \left( 1 - \left( \frac{\alpha_1}{T_K} \right)^2 \left( \frac{2e^2 V}{9} + \frac{C^2(e^2 V)^2}{6} + \frac{5(\pi T)^2}{9} \right) \right), \]

\[ (35) \]

where \( I_m = (4e^2V/h)(1-C^2) \).

Turning now to the SU(4) case with one electron on the dot, one finds that the inelastic contribution to the current vanishes identically [cf. Eq. (32)], as the “effective charges” associated with interaction-induced scattering events are proportional to \( \cos \theta \delta_0 \) and hence identically zero.\(^{25} \) The only contribution is thus from the elastic channel [cf. Eq. (22)], yielding

\[ I = I_m \left( 1 - \frac{\alpha_1 eV}{T_K} - \frac{\alpha_2}{3} \left( \frac{e^2 V}{2} \right)^2 (1-3C^2) \right), \]

\[ (36) \]

where \( I_m = (2e^2V/h)(1-C^2) \). There is no temperature correction up to this order of the low-energy expansion. The case with three electrons \((m=3)\) and SU(4) symmetry is related to the one-electron case by particle-hole symmetry. The Kondo resonance is thus changed from above to below the Fermi energy. The result for the current is then the same as Eq. (36) but with an opposite sign for the asymmetry \((\theta \rightarrow \pi/2 - \theta, C \rightarrow -C)\), i.e., the roles of left (L) and right (R) leads are exchanged for hole transport.

The differential conductance \( G(V) = \frac{dI}{dV} \) obtained from Eq. (36) gives an asymmetric curve whenever \( C \neq 0 \). Consider the first the strongly asymmetric case, where \( |C| \) becomes sizeable. In this case, the asymmetric linear \( eV/T_K \) correction in Eq. (36) dominates even at low bias voltage. For strong asymmetry \( |C| \rightarrow 1 \), the conductance measures the density of states of the Kondo resonance\(^{50} \) at \( \pm eV \). The asymmetric linear term thus follows the side of the Kondo resonance and reveals that the resonance peak is located away from the Fermi level.\(^{15} \) This behavior is in fact generic to the SU(N) case when the occupation of the dot is away from half filling. In the SU(2) case or generally for a half-filled dot \((m=N/2)\), the resonance peak is located at the Fermi level which suppresses the asymmetric linear term, see Eqs. (34) and (35).

Turning now to the case of a symmetric dot-lead coupling \((C=0)\), we see that as expected, the differential conductance \( G(V) \) is symmetric in \( V \) at all dot fillings; hence, it exhibits a quadratic behavior at low bias. In the SU(4) case, the conductance obtained from Eq. (36) is predicted to be maximum at \( V=0 \), in agreement with results obtained from slave-boson mean-field theory.\(^{27} \) Within the Fermi-liquid approach, and for one electron on the dot, this behavior is at first glance rather puzzling. As we have already indicated, in the SU(4) case, the conductance is completely due to the elastic transport channel. Using the heuristic picture provide by the resonant-level picture (i.e., elastic scattering due to a Lorentzian Kondo resonance sitting above the Fermi energy), one would expect that the differential conductance should increase with increasing voltage, due to the positive curvature of the expected (Lorentzian) transmission coefficient. This picture is in fact incorrect as it neglects the important Hartree contributions discussed in Sec. III B. Heuristically, as the voltage is increased, quasiparticle interactions lead to a mean-field upward energy shift of the position of the Kondo resonance. Because of the relation \( \phi_2 = (4/3)\alpha_2 \), this energy-shift effect dominates and causes the conductance to decrease; without this mean-field energy shift, the conductance would indeed exhibit a quadratic increase at small voltages. Note that an incorrect upturn in the conductance was reported in previous works: Ref. 25 neglected the higher-order Fermi-liquid interaction parameter \( \phi_2 \) and the resulting mean-field energy shift while Ref. 24 treated it incorrectly (corrected in Ref. 28). Note also that the results for the conductance presented in Ref. 12 only apply to a system with a strongly asymmetric dot-lead coupling.

### IV. CURRENT NOISE

Fluctuations in the current are almost as important as the current itself. In particular, the shot noise (at zero temperature) carries information about charge transfer in the mesoscopic system. The purpose of this section is to detail the calculation of the zero-frequency current noise

\[ S = 2 \int dt \langle \Delta \hat{I}(t) \Delta \hat{I}(0) \rangle \]

(37)

with the current fluctuation \( \Delta \hat{I}(t) = \hat{I}(t) - \langle \hat{I}(t) \rangle \), see Eq. (16) for the current operator expression.

Insight can be gained by first examining the strong-coupling fixed point at zero temperature with \( eV \ll T_K \) so that \( \delta_0 \approx \delta_0 \). Quantum expectations in Eq. (37) are evaluated with the free Hamiltonian (8). The shot noise
is pure partition noise like a coherent scatterer.\textsuperscript{46} This result implies a vanishing noise in the particle-hole symmetric case, such as standard SU(2), with symmetric leads coupling ($T_0=1$ and $C=0$). In this specific case, the shot noise is only determined by the vicinity of the Kondo strong-coupling fixed point, that is, by the inelastic Hamiltonian (9) and the corrections to $\delta_0$ in the elastic phase shift Eq. (6). The shot noise is therefore highly nonlinear with $S=V^3$ at low bias voltage. Since the corresponding current is close to unitarity, an effective charge $e^*=\langle 5/3 \rangle e$ has been extracted from the ratio of the noise to the backscattering current.\textsuperscript{23} $e^* = e$ should however not be confused with a fractional charge. It emerges as an average charge during additional and independent Poissonian processes involving one and two charges transfer as shown by the calculation of the full counting statistics.\textsuperscript{48} Nevertheless, this charge $e^* = \langle 5/3 \rangle e$ is universal and characterizes the vicinity of the Kondo strong-coupling fixed point. It can be seen as an out-of-equilibrium equivalent of the Wilson ratio.

In asymmetric situations ($T_0 \neq 1$ or $C \neq 0$), the linear part Eq. (38) of the noise does not vanish and even dominates at low bias voltage. For instance in the SU(4) case, $T_0=1/2$ so that $T_0(1-T_0)=1/4$. This property is quite relevant for experiments and may be used to discriminate SU(2) and SU(4) symmetries for which the current gives essentially the same answer.\textsuperscript{27} In a way similar to the symmetric SU(2) case, we can define an effective charge from the ratio of the nonlinear parts ($-V^3$) in the noise and the current.\textsuperscript{24,25} This is however less straightforward to measure experimentally since it requires a proper subtraction of the linear terms.

\section{A. Elastic contribution to the noise}

Inserting the current operator Eq. (16) in Eq. (37), the elastic Hamiltonian (8) gives a Gaussian measure which allows to use Wick's theorem, and thus Eqs. (17). Like for the current, we obtain a Landauer-Büttiker formula\textsuperscript{46} for the noise with the same transmission Eq. (19) and phase shift Eq. (20). At zero temperature, it reads

$$S_0 = \frac{2Ne^2}{h} [V]_0 (1 - C^2)(1 - T_0(1 - C^2)] \quad (38)$$

is pure partition noise like a coherent scatterer.\textsuperscript{46} This result implies a vanishing noise in the particle-hole symmetric case, such as standard SU(2), with symmetric leads coupling ($T_0=1$ and $C=0$). In this specific case, the shot noise is only determined by the vicinity of the Kondo strong-coupling fixed point, that is, by the inelastic Hamiltonian (9) and the corrections to $\delta_0$ in the elastic phase shift Eq. (6). The shot noise is therefore highly nonlinear with $S=V^3$ at low bias voltage. Since the corresponding current is close to unitarity, an effective charge $e^* = \langle 5/3 \rangle e$ has been extracted from the ratio of the noise to the backscattering current.\textsuperscript{23} $e^* = e$ should however not be confused with a fractional charge. It emerges as an average charge during additional and independent Poissonian processes involving one and two charges transfer as shown by the calculation of the full counting statistics.\textsuperscript{48} Nevertheless, this charge $e^* = \langle 5/3 \rangle e$ is universal and characterizes the vicinity of the Kondo strong-coupling fixed point. It can be seen as an out-of-equilibrium equivalent of the Wilson ratio.

In asymmetric situations ($T_0 \neq 1$ or $C \neq 0$), the linear part Eq. (38) of the noise does not vanish and even dominates at low bias voltage. For instance in the SU(4) case, $T_0=1/2$ so that $T_0(1-T_0)=1/4$. This property is quite relevant for experiments and may be used to discriminate SU(2) and SU(4) symmetries for which the current gives essentially the same answer.\textsuperscript{27} In a way similar to the symmetric SU(2) case, we can define an effective charge from the ratio of the nonlinear parts ($-V^3$) in the noise and the current.\textsuperscript{24,25} This is however less straightforward to measure experimentally since it requires a proper subtraction of the linear terms.

\section{A. Elastic contribution to the noise}

Inserting the current operator Eq. (16) in Eq. (37), the elastic Hamiltonian (8) gives a Gaussian measure which allows to use Wick’s theorem, and thus Eqs. (17). Like for the current, we obtain a Landauer-Büttiker formula\textsuperscript{46} for the noise with the same transmission Eq. (19) and phase shift Eq. (20). At zero temperature, it reads

$$S_0 = \frac{2Ne^2}{h} \int_{\mu_R}^{\mu_L} d\epsilon T(\epsilon) [1 - T(\epsilon)]. \quad (39)$$

An expansion to second order in $eV/T_K$ yields the elastic (nonlinear) correction to the noise Eq. (38)

$$\frac{\partial S_{\text{el}}}{(1-C^2)2Ne^2 V/h} = \delta_{\text{el}}^{(1)} eV + \delta_{\text{el}}^{(2)} \left( \frac{eV}{T_K} \right)^2 \quad (40)$$

with coefficients

$$\delta_{\text{el}}^{(1)} = - \frac{Ce^2}{2} \frac{2\delta_0}{1 - 2T_0(1 - C^2)}, \quad (41a)$$

\section{B. Inelastic contribution to the noise}

We follow the same procedure as for the interaction correction to the current established in Sec. III C. The mean value in Eq. (37) is taken within the Keldysh framework, similar to Eq. (23). The correct ordering of $\hat{I}$ operators is maintained by choosing time 0 on the $\eta=+$ branch and time $t$ on the $\eta=-$ branch. The perturbative study of the noise involves diagrams with two current vertices instead of one in Sec. III C. The resulting calculations are therefore similar to those for the current but are much more involved on the technical side. The diagrams relevant for the noise at first and second order in $1/T_K$ are shown Fig. 4. Noninteracting Green’s functions are still given by Eqs. (24).

Three vertices can be built from the interaction Hamiltonian $H_{\text{int}}$ (9) with coefficients $\phi_1$, $\phi_2$, and $\chi_3$. The $\chi_3$ vertex has six legs and appears at most once at order $1/T_K^3$. Topology therefore imposes that two legs among the six must connect to form a closed loop. The corresponding energy inte-
where the different terms are respectively given by Eqs. 4 to get $A$ where $eV$ order in $eV$

This general expression can finally be expanded order by order in $eV/T_K$. After energy integration, we obtain at zero temperature a first and a second-order noise term

$$\frac{\delta S_{\text{int}}}{(1-C^2)2Ne^2/h} = \frac{\phi_1(N+1)}{T_K} \int d\varepsilon d\varepsilon' \Delta f(\varepsilon) \phi(\varepsilon,\varepsilon') \Delta f(\varepsilon') \sin 2\theta(\varepsilon').$$

(43)

This general expression can finally be expanded order by order in $eV/T_K$. After energy integration, we obtain at zero temperature a first and a second-order noise term

$$\frac{\delta S_{\text{int}}}{(1-C^2)2Ne^2/h} = \frac{\phi_1(N+1)}{T_K} \int d\varepsilon d\varepsilon' \Delta f(\varepsilon) \phi(\varepsilon,\varepsilon') \Delta f(\varepsilon') \sin 2\theta(\varepsilon').$$

(44)

with coefficients

$$\delta S_{\text{int}}^{(a,1)} = C\phi_1(N+1)\sin 2\theta_0 \sin^2 \theta_0,$$

$$\delta S_{\text{int}}^{(a,2)} = -C^2(N+1)\phi_2 \sin 2\theta_0 + 6\alpha_1\phi_1 T_0 (1-4T_03)\big/2.$$ (45a, 45b)

Note that these two terms vanish identically for symmetric leads coupling ($C=0$). It can be checked again that the first-order correction is odd with respect to particle-hole symmetry while the second order is even.

The expansion to second order in $H_{\text{int}}$ yields the Figs. 4(b)–4(f) with two interaction vertices. To be consistent with the rest of the perturbative calculation, only $\phi_1$ is kept in each interaction vertex. The contributions corresponding to Figs. 4(b)–4(f) are all calculated in Appendix C. Finally, the total noise reads

$$S = S_0 + \delta S_{\text{el}} + \delta S_{\text{int}}^\alpha + \delta S_{\text{int}}^\beta + 2\delta S_{\text{int}}^c + \delta S_{\text{int}}^\gamma + \delta S_{\text{int}}^f,$$ (46)

where the different terms are respectively given by Eqs. (38), (40), (44), (C19), (C12), (C16), and (C6).

C. Noise for SU(2) and SU(4)

We have also extended the noise calculation to finite temperature along the lines of Appendix B. In the asymmetric case, the results are too cumbersome to be written here. In the symmetric case, the noise was calculated in Ref. 24 where it was emphasized that corrections are rapidly sizeable at finite temperature. Hence the shot-noise regime is expected only at very low temperature. Keeping a zero temperature, we specialize here to the experimentally relevant SU(2) and SU(4) cases with one electron on the dot, $m=1$.

In the SU(2) case, the noise correction to Eq. (38) reads

$$\frac{\delta S}{(1-C^2)2Ne^2/h} = \frac{(eV)^2}{T_K} \alpha_1^2 \big/ \left( \frac{5}{6} - 3C^2 \right),$$ (47)

where the $C^4$ terms cancel each other unexpectedly.

In the SU(4) case, the noise correction has linear and quadratic contributions

$$\frac{\delta S}{(1-C^2)2Ne^2/h} = \frac{(eV)^2}{T_K} \alpha_1^2 \big/ \left[ \frac{18}{(1-8C^2+7C^4)} - \frac{81}{6} (1-3C^2) \right].$$ (48)

V. RESULTS AND CONCLUSION

A. Main Results

Following Refs 24 and 25, we define a generalized Fano factor $F$ which describes the relation between the nonlinear current and current noise

$$F = \frac{\frac{1}{2e} \frac{\delta S}{\delta I} \big/ \delta I}.$$ (49)

It is defined as the ratio between the nonlinear parts of the noise $\delta S = S - S_0$ [cf. Eq. (38)] and of the current $\delta I = I - I_0$, where

$$I_0 = (1-C^2)NT_0 e^2 V/h$$ (50)

is the linear current (for $eV \ll T_K$). We focus on the nonlinear noise and current as it is these quantities which are sensitive to the contribution of Fermi-liquid interactions.

Consider first the strong asymmetric case $|C| \rightarrow 1$ (i.e., $\theta \rightarrow 0$ or $\theta \rightarrow \pi/2$), where the dot is strongly coupled to one lead and only weakly to the other [cf. Eq. (2)]. Transport in this limit corresponds to an incoherent tunneling regime where the hopping from the weakly coupled lead to the dot is the limiting process. It can be checked from the Eqs. (40), (44), (C19), (C12), (C16), and (C6) for the noise, and Eqs. (22) and (32) for the current, that the Fano factor $F = 1$ to leading order in $1-|C|$. This is of course expected since the tunneling regime gives Poissonian statistics for charge transfer. Note that this unity ratio holds order by order for the $eV/T_K$ and $(eV/T_K)^2$ correction separately. In addition, we also have $S_0/2eI_0 = 1$ to leading order in $1-|C|$. In the opposite limit of a symmetric dot-lead coupling (i.e., $C=0$), coherent effects are important to transport, and charge transport is generally not Poissonian.48 Note also that in the symmetric case, the nonlinear parts of both the current and current noise are $\propto V^3$. We find that the generalized Fano factor Eq. (49) is given by

155322-10
We give in Table I values of the partition noise associated with single-particle scattering. We stress that the fact the conductance is close to unitarity and interactions play no role in electronic transmission of quantum dots. One important characteristic of the emergent Kondo regime is the sign change in the leading current corrections due to the asymmetry of the coupling to the leads. In this limit, the Wilson ratio is in fact just one. however, the effect of two-particle scattering processes seems to survive in the current noise through the diagram of Fig. 4(b). Heuristically, this diagram represents an enhancement of the coherent partition noise already present in the absence of Fermi-liquid interactions. The small interaction parameter $\delta_0^2 \sim 1/N^2$ is compensated by the spin summation with $\sim N^3$ equivalent diagrams. The effect is therefore linear in $N$, at the same level as elastic terms.

The expression of Eq. (52) can be checked in two limiting cases. For $\delta_0 \rightarrow 0$, it gives $F = 1$. Again it corresponds to the tunneling regime since a small phase shift $\delta_0$ implies a weak electronic transmission $T_0 = \sin^2 \delta_0$. When particle-hole symmetry is recovered, $\delta_0 = \pi/2$, we find $F = -1$. In this limit, the conductance is close to unity and interactions play no role since the diagram of Fig. 4(b) gives a vanishing contribution for $\delta_0 = \pi/2$. The situation is therefore similar to the ordinary SU(2) case where one has Poissonian weak backscattering events. In our case though, backscattering events are elastic and imply the transfer of only one electron so that $F = -1$.

We finally turn to the general asymmetric case, $C \neq 0$, where we focus on the SU(2) and SU(4) symmetries with $m = 1$. For SU(2), the generalized Fano factor is obtained from the ratio of the noise Eq. (47) and current Eq. (34) corrections at zero temperature. We stress that this simple result Eq. (53) is exact and is not restricted to small values of the asymmetry $C$. Equation (53) indeed bridges the symmetric result $F = -5/3$ (Ref. 23) to the tunneling regime, $F = 1$ in the strong asymmetry limit $C \rightarrow 1$. A different asymmetry correction was predicted in Ref. 23. This discrepancy may come from the fact that the current expression used in Ref. 23 is not valid outside the symmetric case $C = 0$ (see discussion at the end of Sec. III A). The SU(4) case for arbitrary asymmetry is more complicated since the generalized Fano factor Eq. (49) bears an $eV/T_K$ dependence. This is because the nonlinear current and noise have both linear and quadratic corrections in $eV/T_K$ (respectively, quadratic and cubic terms in $V$) and no simplification occurs when the ratio is computed (universality is however recovered in the symmetric case where the linear corrections vanish). We therefore prefer to compute directly the ratio of the quadratic corrections with the result

$$F^{(2)} = \frac{1}{2e} \frac{\delta S^{(2)}}{\delta I^{(2)}} = -\frac{\delta_1^2}{3\alpha_2} \frac{2}{1 - 3C^2} + C^2,$$  

(54)

where $\delta S^{(2)}(\delta I^{(2)})$ denotes the noise (current) correction to second order in $eV/T_K$. Again the ratio Eq. (54) connects the symmetric case $(N = 4$ and $m = 1$ in Table I), $F^{(2)} = -\frac{\alpha_1}{3\alpha_2} = -0.300$ (Ref. 28) to the tunnel or strongly asymmetric regime where $F^{(2)} = 1$. Expanding Eq. (54) in $C$, we obtain $F^{(2)} = -0.300(1 - 8.33C^2)$ which indicates an important correction due to the asymmetry of the coupling to the leads.

</table>

This Fano factor includes the effect of interactions; we have used the important equalities in Eqs. (11). Note that this result has no explicit dependence on $V/T_K$: it is thus a universal quantity characterizing the Fermi-liquid properties of the strong-coupling fixed point; also note that $F$ is invariant under a particle-hole transformation, where $m \rightarrow N - m$. We stress that the fact $F \neq 1$ in general is due both to the presence of two-particle scattering at the fixed point as well as to the partition noise associated with single-particle scattering. We give in Table I values of $F$ for different $N$ and $m$.

For $N \rightarrow +\infty$, Eq. (51) leads to

$$F = \frac{3 \cos 2\delta_0 + 4 \cos 2\delta_0 - 1}{4 + 2 \cos 2\delta_0}.$$  

(52)

Note that in the large $N$ limit, two-particle scattering processes become insignificant for the current (since $\delta_0$ and $\phi_0$ scale as $-1/N$) and the result is consistent with the noninteracting resonant level. In this limit, the Wilson ratio is in fact just one.

B. Conclusion

To summarize, we have provided a thorough analysis of the nonequilibrium transport in the SU(N) Kondo regime using an elaborate Fermi-liquid approach. We have particularly focused on the case $N = 4$ relevant to carbon nanotube quantum dots. One important characteristic of the emergent SU(4) symmetry is the sign change in the leading current corrections (i.e., linear in $eV/T_K$) as a function of the bias voltage when progressively tuning the asymmetry between the dot-lead couplings. More precisely, for a strong asymmetry, we have recovered a positive linear correction which traduces the fact that the Kondo resonance is peaked away from the Fermi level; in this case, the conductance measures
the density of states of the Kondo resonance at $\pm eV$ where the sign changes with the weakly coupled lead. For symmetric couplings, we have demonstrated that the linear correction now becomes exactly zero and that the current becomes maximum at $V=0$ due to interactions via the Hartree contributions. In addition, the noise exhibits a nontrivial form due to the interplay between coherent shot noise and noise arising from interaction-induced scattering events. In the symmetric case, interactions result in a universal Fano factor $F \approx -0.300$ at zero temperature. For a finite asymmetry between dot-lead couplings, the current and the noise have both linear and quadratic corrections in $eV/T_K$. Focusing exclusively on the quadratic corrections, we have derived a formula for the Fano factor which extrapolates between the symmetric result and the strongly asymmetric result $F=1$, perfectly reproducing the Poissonian statistics for charge transfer in the tunneling limit.

In the context of the standard SU(2) Kondo effect, we have obtained a generalized Fano factor $F=-5/3+8C^2/3$ at zero temperature which is not restricted to small values of the asymmetry. Finally, in the limit of large $N$, it is certainly relevant to observe that the effect of interactions tends to subside in the current noise.

APPENDIX A: COUNTERTERMS AND MODEL RENORMALIZATION

The improper self-energy can be calculated to second order in $eV/T_K$ following Refs. 12 and 31. The result is that the dependence on the cutoff $D$ can be removed by adding the counterterm

$$H_{c,1} = -\frac{1}{2\pi i T_K} \sum \delta\alpha_1 (\varepsilon_k + \varepsilon_{k'}) b_{\sigma k}^\dagger b_{\sigma' k'}$$

$$\delta\alpha_1 = -\frac{\phi_f}{T_K} \frac{6D}{\pi} \ln \left( \frac{4}{3} \right)$$

(A1)

to the Hamiltonian $H_0 + H_{int}$, Eqs. (8) and (9). It corresponds to a renormalization of $\alpha_1 \rightarrow \alpha_1 + \delta\alpha_1$.

We will now show that the second contribution that arises from Eq. (28), and that we have discarded in Sec. III C, produces a term linear in $D$ exactly cancelled by the counterterm Eq. (A1). Using the identity $\Sigma^+(t) - \Sigma^-(t) = \text{sgn}(t) [\Sigma^{-}(t) - \Sigma^{-}(t)]$, it takes the form

$$\delta I_{\text{int}}^{(2)} = N(N-1)(1-C^2) e^{\pi} \left( \frac{\phi_f}{\pi \nu^2 T_K} \right)^2 S \times \int dt \text{sgn}(t) (\Sigma^+ - \Sigma^-)(t)i\pi \nu \Delta f(-t) + \text{c.c.},$$

(A2)

where $\Delta f(t)$ is the time Fourier transform of $\Delta f(e) = f_L(e) - f_R(e)$. Inserting the Fourier transform of $F_0 \pm 1$

$$\int_{-D}^{D} \frac{de}{i} (F_0(e) \pm 1) e^{-i\omega t} = \frac{\pi T}{\sinh(\pi T t)} (2\cos^2 \theta e^{-i\mu t})$$

$$+ 2 \sin^2 \theta e^{-i\mu t} - \frac{2e^{\pm iDt}}{t}$$

(A3)

in Eq. (25) with Eq. (24a), it can be checked that intermediate values of $t \sim 1/T, 1/V$ give a vanishing result for Eq. (A2) (integral is odd in $t$). Equation (A2) is therefore dominated by small $t \sim 1/D$. In that limit, $\Sigma^{-}(t) = \nu^3 (1-e^{D\mu}/1)^{-1/2}$ and $\Sigma^{-}(t) = [\Sigma^{-}(t)]^*$. $\Delta f(t) = \Delta f(0) + i\Delta f'(0)$ is expanded to first order in $t$ since the zeroth order gives an odd integrand and a vanishing integral. After some straightforward algebraic manipulations, we eventually find the result

$$\frac{\delta I_{\text{int}}^{(2)}}{(1-C^2)N\nu \hbar} = -\text{sin} 2\delta_0 \int d\omega \frac{\delta\alpha_1 e^\omega}{\omega} [f_L(e) - f_R(e)],$$

(A4)

where we have used that

$$\text{Im} \int_0^{\pm \infty} (du/\nu^2)(1-e^{\nu u})^3 = 3 \ln(3/4).$$

When higher orders in $t$ are included in the expansion, corrections to Eq. (A4) are of order $O(1/D)$ and completely vanish in the universal limit $D \rightarrow +\infty$. In particular, the $O(1)$ contribution vanishes by symmetry. Finally, the counterterm Eq. (A1) gives an elastic contribution to the current that can be computed along the lines of Sec. III B. The result compensates exactly Eq. (A4).

A second counterterm is generated by vertex corrections. In the spirit of the self-energy calculation, the singular contributions (i.e., depending on the cutoff $D$) to the four-particle vertex are determined from the standard second-order diagrams shown in Fig. 5 and proportional to $\phi_f^2$. This strong dependence on $D$ is removed by the counterterm

$$H_{c,2} = \frac{\delta\phi_f}{\pi \nu^2 T_K \nu <\sigma' \sigma, k'>} :b_{\sigma k}^\dagger b_{\sigma' k'} b_{\sigma' k} b_{\sigma k}^\dagger :,$$

FIG. 5. $\phi_f^2$ corrections to the four-particle vertex.
To summarize, the perturbative calculation of observables to second order in \( e/\hbar T \) (\( e \) is a typical energy, \( \mu_B B, k_B T, \) or \( eV \)) from the full Hamiltonian \( H_0 + H_{\text{int}} + H_{c,1} + H_{c,2} \), leads to finite and well-defined results in the universal limit \( D \to \pm \infty \).

**APPENDIX B: FINITE TEMPERATURE CURRENT**

We briefly outline how the current is calculated at finite temperature. For the elastic part Eq. (18) detailed in Sec. III B, we merely need the Fourier transform of \( \Delta f(e) \) to define the current.

\[
\Delta f(t) = (e^{-i\mu t} - e^{-i\mu t'}) \frac{i \pi T}{2 \pi \sinh(\pi T t)} .
\]

(B1)

The derivatives of \( \Delta f(t) \), taken at \( t=0 \), give access to the integrals with the corresponding powers of \( e \) in Eq. (18).

The inelastic part of the current is detailed in Sec. III C and given by Eq. (29). Equation (29) is evaluated at finite temperature by Fourier transform to real time \( t \). The time contour is then shifted by \( i \eta \) in the complex plane with \( \eta D > 1 \) (but \( T, eV \ll 1/\eta \)) such as to suppress the dependence on the cutoff \( D \) in Green’s functions. From Eq. (A3), the result is (for \( x=0 \))

\[
\mathcal{G}^{\pm}_{bb}(t) = -i (e^{-i\mu t} + e^{-i\mu t'}) \frac{\pi T}{\sinh(\pi T t)} .
\]

with a similar expression for \( \mathcal{G}^{+\pm}_{bb}(t) \). The intermediate integral result

\[
\int_{-\infty + i\eta}^{+\infty + i\eta} dt \mathcal{G}^{\pm}_{bb}(t) \mathcal{G}^{\mp \pm}_{bb}(-t) \mathcal{G}^{\pm \pm}_{bb}(t) = \pi \nu \Delta f(-t)
\]

is used to derive the current correction

\[
\frac{\delta I_{\text{int}}}{(1 - C^2)Nc^2V/h} = 2 \sin \theta_0(N - 1) \left( \frac{\phi_1}{T K} \right)^2 \times \left[ \left( \frac{5}{12} - \frac{C^2}{4} \right) (eV)^2 + \frac{2(\pi T)^2}{3} \right] .
\]

(B3)

The \( t \) integral in Eq. (B2) is obtained by first expanding the numerator in powers of \( e^{\pm i\mu t} \). Each term gives an integral. The standard method to evaluate such integrals is to shift the integration contour by \( -i/T \) in the complex plane which encloses the pole at \( x=0 \).

**APPENDIX C: DETAILS ON THE INTERACTION CORRECTION TO THE NOISE**

We discuss in this Appendix the interaction corrections to the noise with two interaction vertices, i.e., Figs. 4(b)–4(f).

Terms \( \approx \phi_2 \chi_2 \) in the interaction Hamiltonian (9) are already second order in \( 1/T_K \). Therefore only the term \( \approx \phi_1 \) is kept for Figs. 4(b)–4(f) since the whole calculation goes up to second order in \( 1/T_K \).

In order to simplify the forthcoming expressions, let us define the following prefactor

\[
S_p = \frac{hN(N - 1)\sin^2 \theta}{\pi} \left( \frac{e}{2 \nu h} \right)^2 \left( \frac{\phi_1}{\pi \nu^3 T K} \right)^2 .
\]

(C1)

We start by considering Fig. 4(f) where the self-energy bubble is inserted in the top Green’s function. Going to energy space and integrating over time \( t \) in Eq. (37), the corresponding contribution takes the form

\[
\delta S^{\phi_1}_{\text{int}} = \sum_{\eta, \eta_1} \eta \eta_1 \int \frac{d e}{2 \pi} \frac{\eta \eta_1 (e)}{P_{\eta, \eta_1}(e)} F_{\eta, \eta_1}(e) ,
\]

(C2)

where \( P_{\eta, \eta_1}(e) \) is the self-energy part Eq. (25) that already appeared in the calculation of the current. \( P_{\eta, \eta_1} \) is a notation for the product of the three Green’s functions (of the form \( G^{\eta} G^{\eta_1} G^{\eta_2} \)) that enclose the self-energy in Fig. 4(f). Since the current operator Eq. (16) has four different terms, this gives a sum of 16 terms for \( P_{\eta, \eta_1} \). Yet nine of these terms have no \( \eta, \eta_1 \) dependence and vanish when summed over \( \eta, \eta_1 \). This is a consequence of the causality identity (26).

Finally \( P_{\eta, \eta_1} \) reads

\[
P_{\eta, \eta_1}(e) = (-S') G^{\eta}_{ab}(x, e) G^{\eta_2}_{ba}(x, e) G^{\eta_1}_{ba}(x, e) + \cdots
\]

(C3)

The noise contribution with a bottom self-energy insertion gives a similar expression. Green’s functions are replaced by their expression (24) and the summation over \( \eta, \eta_1 \) is performed together with the causality identity (26). In analogy with the current calculation, two sorts of terms are obtained: (i) those including the combination \( \Sigma' + \Sigma'' \) and (ii) those with \( \Sigma' \) or \( \Sigma'' \). Type (i) terms are dominated by energies on the order of the model cutoff \( D \). They are exactly cancelled by the counterterm Eq. (A1). We therefore only keep type (ii) terms. Combining top and bottom self-energy insertion diagrams, \( \delta S^{\phi_1}_{\text{int}} = \delta S^{\phi_2}_{\text{int}} = \delta S^{\phi_3}_{\text{int}} = \delta S^{\phi_4}_{\text{int}} \) we find the contribution

\[
\delta S^{\phi_1}_{\text{int}} = \delta S^{\phi_2}_{\text{int}} = \delta S^{\phi_3}_{\text{int}} = \delta S^{\phi_4}_{\text{int}} = \frac{i}{2} \left[ (1 - C^2)(\cos 4 \delta_0 - 2 \cos \delta_0 [\Delta f(e)]^2) + \cdots \right] ,
\]

(C4)

At zero temperature, \( F_{\theta}(e) F_{\theta}(e) - 1 = -(1 + C^2) \Delta f(e) - \cdots \)
early on the cutoff $D$ and are exactly cancelled by counter-terms. This will be discussed at the end of this Appendix.

We are left with

$$
\frac{\delta S'_{\text{int}}}{(1 - C^2)2Ne^2}/h = \frac{\pi(N-1)(1-C^2)\phi_1^2}{2\nu^2 T_K^2} \int \frac{\text{d}e_1}{2\pi} \int \frac{\text{d}e_2}{2\pi} \Delta f(e_1) \Delta f(e_2) \left\{ \Pi^+_{\eta_1 = \eta_2} \cos 4\delta_0 + 2\Pi^+_{\eta_1 = \eta_2} T_0 \cos 2\delta_0 [F_0(e_1) - F_0(e_2)] \right\},
$$

(C11)

At zero temperature, the second term in the brackets gives a vanishing contribution. Developing in terms of Fermi step functions, the integrals over energies can be performed leading to

$$
\frac{\delta S'_{\text{int}}}{(1 - C^2)2Ne^2}/h = \frac{\pi(N-1)\phi_1^2}{2\nu^2 T_K^2} (1 - C^2) \left( \frac{1}{6} + \frac{C^2}{12} \right)
$$

(C12)

corresponding to the combination $J_2(1+C^2) + 4J_1 C^2$.

Figure 4(d) gives exactly the same contribution, $\delta S'_{\text{int}} = \delta S'_{\text{int}}$. The calculation for Fig. 4(e) is quite similar with the introduction of the particle-particle bubble

$$
\Pi^\eta_1,\eta_2(t) = \sum_{k_1, k_2} G^\eta_1,\eta_2(k_1, t) G^\eta_2,\eta_1(k_2, t)
$$

(C13)

that satisfies the same causality identity (C8). The noise term reads

$$
\delta S'_{\text{int}} = S_P \sum_{\eta_1, \eta_2} \eta_1 \eta_2 \int \frac{\text{d}e_1}{2\pi} \int \frac{\text{d}e_2}{2\pi} \Delta f_{\eta_1, \eta_2}(e_1) \times \Pi^\eta_1,\eta_2(e_1 + e_2) A_{\eta_1, \eta_2}(e_2)
$$

(C14)

leading to

$$
\frac{\delta S'_{\text{int}}}{(1 - C^2)2Ne^2}/h = -\frac{\pi(N-1)\phi_1^2}{2\nu^2 T_K^2} \int \frac{\text{d}e_1}{2\pi} \int \frac{\text{d}e_2}{2\pi} \Delta f(e_1) \Delta f(e_2) \left\{ \Pi^+_{\eta_1 = \eta_2} + \Pi^-_{\eta_1 = \eta_2} \right\} T_0 \cos 2\delta_0 [F_0(e_1) + F_0(e_2)]
$$

(C15)

and

$$
\frac{\delta S'_{\text{int}}}{(1 - C^2)2Ne^2}/h = (N-1)\phi_1^2 \left( \frac{eV}{T_K} \right)^2 (1 - C^2) \left( \frac{1}{6} + \frac{C^2}{12} + T_0 \cos 2\delta_0 c^2 \right)
$$

(C16)

corresponding to the combination $J_2(1+C^2) - 4J_1 C^2$.
The noise correction for Fig. 4(b) that also involves the particle-hole bubble $\Pi$

$$\delta \phi^0_{\text{int}} = -S_p(N-1) \sum_{\eta_1 \eta_2} \frac{d \epsilon_1}{2\pi} \times \left( \int \frac{d \epsilon_2}{2\pi} A_{\eta_1 \eta_2}(\epsilon_1) \Pi_{\eta_1 \eta_2}(0) A_{\eta_2 \eta_2}(\epsilon_2) \right)$$

(C17)

with the definitions Eqs. (C1), (C7), and (C9). Keeping only the terms with $\Pi^\pm \pm$, we obtain

$$\frac{\delta \phi^0_{\text{int}}}{(1 - C^2)2N e^2/\hbar} = (1 - C^2)\sin^2(2\delta_0) \frac{\pi(N-1)}{\nu^2 T^2_k} \int \frac{d \epsilon}{2\pi} \Delta f(\epsilon) \left( \Pi_{\eta_1 \eta_2}^\pm + \Pi_{\eta_2 \eta_2}^\pm \right).$$

(C18)

At zero temperature, $\Pi_{\eta_2}^\pm = \Pi_{\eta_2}^\pm = (\pi C^2/2)(eV/(1 - C^2))$ so that the noise correction for Fig. 4(b) finally reads

$$\frac{\delta \phi^0_{\text{int}}}{(1 - C^2)2N e^2|V|/\hbar} = \frac{(N-1)}{4} \frac{\delta_0^2}{\nu^2 T^2_k} \left( \frac{eV}{T_k} \right)^2 (1 - C^2)^2.$$

(C19)

Before concluding this long Appendix, we briefly discuss the remaining terms resulting from the $\Pi^\pm - \Pi^\pm - \Pi^\pm$ combinations. They lead to contributions that are linear in the cutoff $D$ with corrections scaling as $O(1/D)$ and therefore vanishing in the universal limit. The calculation is straightforward and uses the same ingredients as in the Appendix A, i.e., small $t$ dominate time integrals. Therefore we can use $\Pi^\pm(t) = -\nu^2 (1 - C^2)/\nu^2$, $\Pi^\pm(t) = -\Pi^\pm(t)$ and $\Pi^\pm(t) = [\Pi^\pm(t)]^*$, $\Pi^\pm(t) = [\Pi^\pm(t)]^*$ in those integrals. The final result reads

$$\frac{\delta \phi^0_{\text{int}}}{(1 - C^2)2N e^2|V|/\hbar} = - \frac{\delta \phi_0(N-1)}{C} \sin \frac{2\delta_0}{\nu^2 T^2_k} \frac{eV}{T_k},$$

(C20)

where we recall that $\delta \phi_0 = (N - 2) \phi_0^0 \frac{D}{\nu^2 T_k} \frac{1}{\pi} \ln 2$. This contribution is exactly cancelled by the counterterm Eq. (A5) included in the diagram of Fig. 4(a).
